# Outline

**What is GWAS / Why GWAS?**

**Unexpected results**

**Non-coding region and function**

**Genetic variants and genome biology**

**Bioinformatics tools**

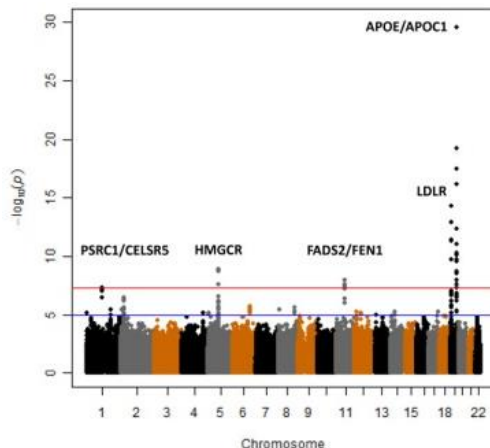

# What is GWAS?

**Unbiased exploration of correlations between SNPs in the human genome and traits**

**Up to 5M SNPs can be analyzed and millions more can be imputed**

**The results are pure statistical correlations**

**Biological interpretations require further experiments**

# What is GWAS?

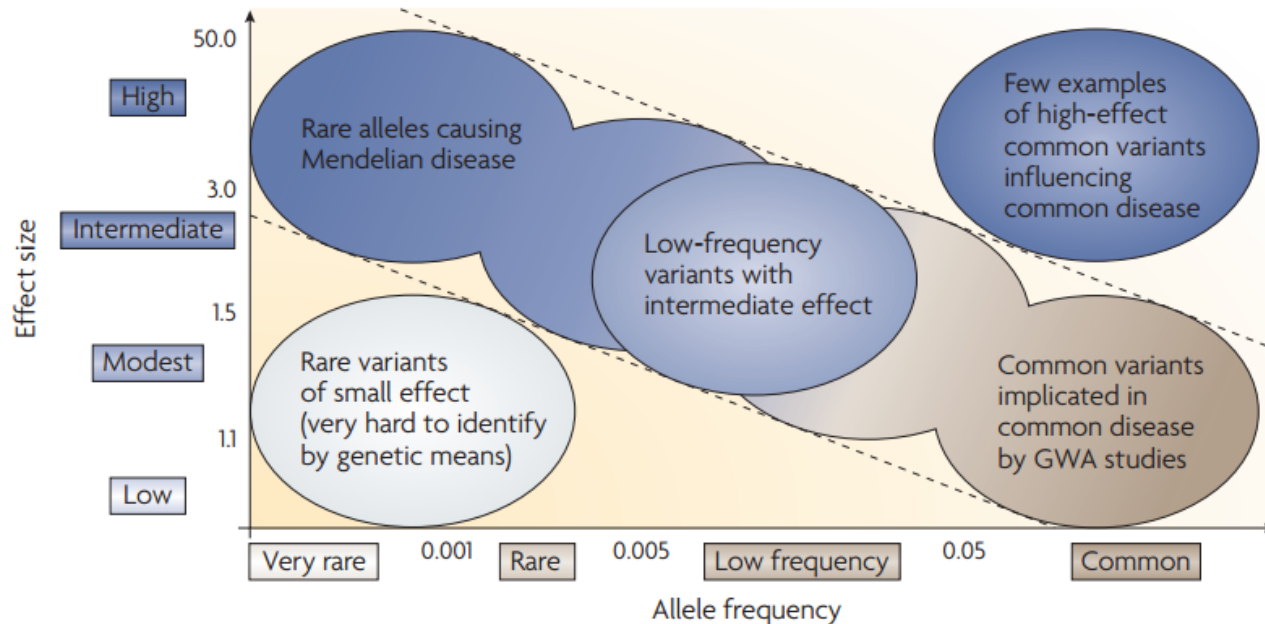

Figure 1 | **Feasibility of identifying genetic variants by risk-allele frequency and strength of genetic effect (odds ratio).** Reproduced, with permission, from *Nature* REF. 10 © (2009) Macmillan Publishers Ltd. All rights reserved. GWA, genome-wide association.

# What is GWAS?

**Figure 1.1. Intermediate mechanisms mediating causal variant's effect on disease susceptibility.**  
Genetic variants modify disease risk by causing changes in gene expression (most common), splicing process or protein structure.

# Why GWAS?

**Genetic association studies have two aims:**

To identify genetic markers that can be used for prediction

To unravel disease biology

# Unexpected Results

**Great majority of results concern the non-coding region**

# Unexpected Results

# Unexpected Results

**Figure 2.** Prostate cancer susceptibility locus is enriched in long noncoding RNAs (lncRNAs). A 1.2 Mb region on chromosome 8q24.21 is a major prostate cancer (PCa)-susceptibility locus. It harbors multiple PCa-associated single-nucleotide polymorphisms (SNPs; shown in pink) and three PCa-associated lncRNAs (prostate cancer associated ncRNA transcript 1 [*PCAT1*], prostate cancer noncoding RNA1 [*PRNCR1*], and Pvt1 oncogene [*PVT1*], all shown in green), and exhibits frequent chromosomal amplification in human cancers. For simplicity, intervening protein-coding genes upstream of the *MYC* oncogene (shown in blue) are not diagrammed. Several microRNA (miRNA) genes colocalize to this region (shown in orange), three of which are housed within the *PVT1* 'host' lncRNA gene. However, no prostate-related functions have yet been ascribed to these miRNAs.

### Abstract

A large noncoding RNA called *ANRIL* (for antisense noncoding RNA in the INK4 locus) has been identified within the *p15/CDKN2B-p16/CDKN2A-p14/ARF* gene cluster. While the exact role of *ANRIL* awaited further elucidation, common disease genomewide association studies (GWAS) have surprisingly identified the *ANRIL* gene as a genetic susceptibility locus shared associated by coronary disease, intracranial aneurysm and also type 2 diabetes. Expression studies have confirmed the coregulation of *p15/CDKN2B*, *p16/CDKN2A*, *p14/ARF*, and *ANRIL*. Among the cluster, *ANRIL* expression showed the strongest association with the multiple phenotypes linked to the 9p21.3 region. More recent GWAS also identified *ANRIL* as a risk locus for gliomas and basal cell carcinomas in accordance with the princeps observation. Moreover, a mouse model has confirmed the pivotal role of *ANRIL* in regulation of *CDKN2A/B* expression through a *cis*-acting mechanism and its implication in proliferation and senescence. The implication of *ANRIL* in cellular aging has provided an attractive unifying hypothesis to explain its association with various susceptibility risk factors. *ANRIL* identification emphasizes the underestimated role of long noncoding RNAs. Many GWAS have identified trait-associated SNPs that fell in noncoding genomic regions. It is conceivable to anticipate that long, noncoding RNAs will map to many of these “gene deserts.”—Pasmant, E., Sabbagh, A., Vidaud, M., Bièche, I. *ANRIL*, a long, noncoding RNA, is an unexpected major hotspot in GWAS.

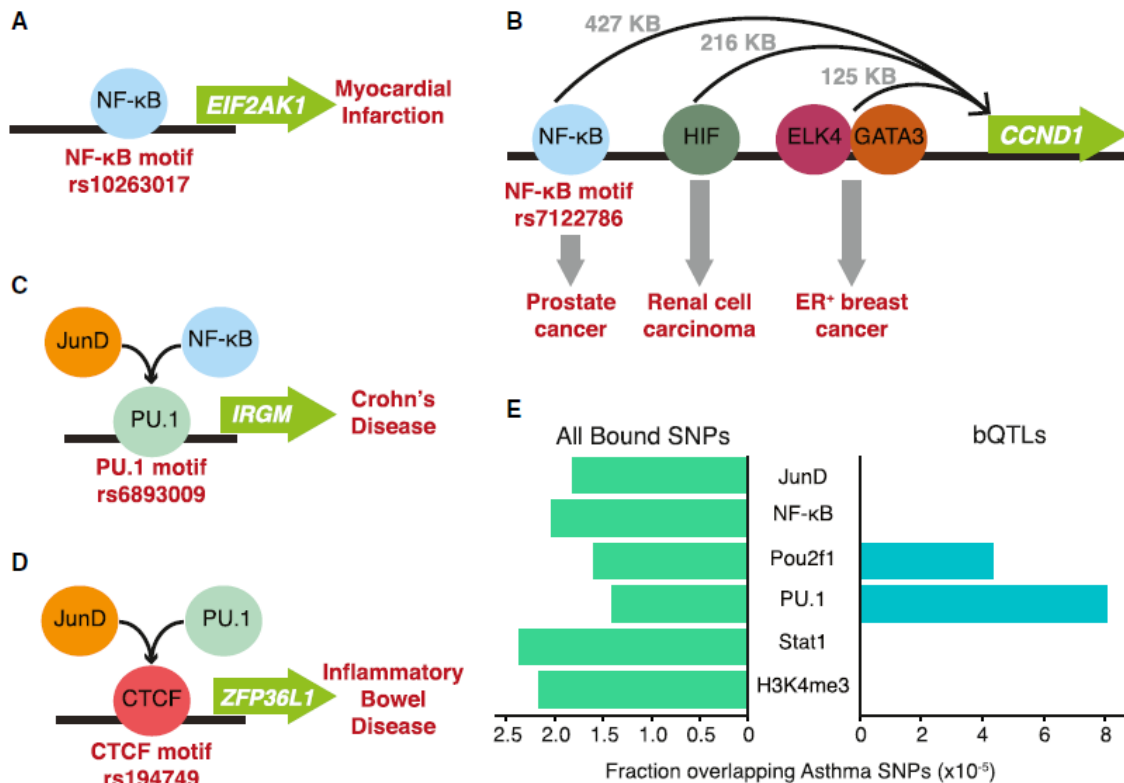

# Genetic Variants and Genome Biology

**Fig. 1. A cascade of regulatory mechanisms by which an eQTL SNP can affect gene expression.** Studies mapping regulatory QTLs have identified a variety of mechanisms, many of which are coordinated, by which eQTLs might act to affect variation in mature mRNA levels. First, eQTL SNPs can impact epigenetic modifications and transcription initiation. These include regulatory processes such as transcription factor binding, histone modifications, enhancer activity (perhaps mediated by chromatin architecture and conformation), and DNA methylation. Transcriptional mechanisms, and specifically transcription factor binding, are likely the strongest contributors to variation in steady-state mRNA levels. Second, recent work has increased appreciation for transcriptional and cotranscriptional processes as major contributors to variation in gene expression levels and mRNA isoform diversity. These include mechanisms such as transcriptional elongation (by PolII traveling rates), cotranscriptional splicing, and mRNA processing and modification. Third, eQTL SNPs both within and outside the transcript have been shown to influence posttranscriptional mRNA processing, which includes mechanisms such as general mRNA degradation, defects in polyadenylation, and targeting by miRNAs. Finally, preliminary studies have shown that we do not yet fully appreciate the extent to which variation in mRNA expression might impact or even correlate to variation in downstream protein products, the synthesis of which are additionally regulated by a set of posttranscriptional and translational mechanisms.

TRENDS in Genetics

## Genetic risk variants can alter chromatin loop formation bridging enhancers and promoters

The human genome is organized in a 3D architecture which is thought to regulate a diverse set of DNA-templated processes [87–91]. This allows regulatory elements, such as enhancers and promoters, to interact physically through long-range chromatin interactions, or chromatin loops, to regulate gene expression [39,42]. The human pigmentation-associated SNP, rs12913832, imposes allele-specific chromatin loop formation [92]. The rs12913832 SNP resides in an enhancer 21 kb upstream of the *OCA2* (oculocutaneous albinism II) pigment gene [92]. The T allele of this SNP favors chromatin loops to the *OCA2* gene compared to the C allele and is associated with a darker pigmentation in melanocytes [92]. Specific DNA binding proteins, including the cohesin and mediator complex as well as the insulator protein CTCF (CCCTC-binding factor), promote chromatin loop formation [93–95]. Although the rs12913832 SNP is the only genetic risk variant known to modulate chromatin loop formation, variants altering the DNA affinity for looping factors will likely also result in allele-specific chromatin loop formation (Figure 2C).

# 3D Genome: Chromatin Interactions

The eukaryotic nucleus is a complex 3D environment in which genome function depends **not only on the linear arrangement of regulatory sequence elements, but also on their spatial organization** for effective control of gene expression.

Analysis of the role of chromatin 3D organization in gene expression is progressing rapidly, largely due to the development of **chromosome conformation capture methods such as Hi-C**.

Sequences within **“Topologically Associated Domains” (TADs)** interact more frequently with sites inside than outside the domain. TADs with a median size of 880 kb have been found in mammals.

## Chromosome folding and its regulation in health and disease

Xue Qing David Wang and Josée Dostie

Spatial chromatin organization as a mechanism to control the expression of genes

### Chromosome folding and its regulation by CTCF and lncRNAs.

Chromosomes occupy distinct territories in the nucleus of mammalian cells (center). The circle represents a view in the nucleus of a cell where three chromosomes (lines) and their territories (highlights) are shown in different colors. Each chromosome sequentially folds into chromatin domains across size scales to guide proper gene expression (top). The orange and green line represents the folding of chromatin into domains (subTAD/TAD/metaTAD) delimited by the cohesin complex and architectural protein CTCF. Areas where the line is orange indicate a domain where transcription is active whereas inactive domains are shown with green lines. Active and inactive domains preferentially interact with each other respectively, and they tend to spatially colocalize in either active (A, orange) or inactive (B, green) compartments. Chromatin organization into domains or compartments as measured with 3C technologies is shown in heatmap form (top right). CTCF and cohesin regulate transcription by various mechanisms including the formation of loop structures that restrict the spread of activating histone marks (left). In the example shown, CTCF binding and dimerization forms a loop structure that contains a cluster of inactive genes (red arrows) silenced by H3K27me3 (pink dots). Formation of this subTAD also serves to prevent further spreading of silencing marks into neighboring regions where genes are active (green arrows). lncRNAs bind histone-modifying complexes to regulate chromatin activity and structure (right). In this example, transcription of a lncRNA gene yields transcripts that recruit chromatin-modifying complexes at nearby genes to silence them while CTCF provides boundaries to limit the scope of this effect. This regulation can occur within chromosomes (*cis*) or between them (*trans*).

# 3D Genome: Chromatin Interactions

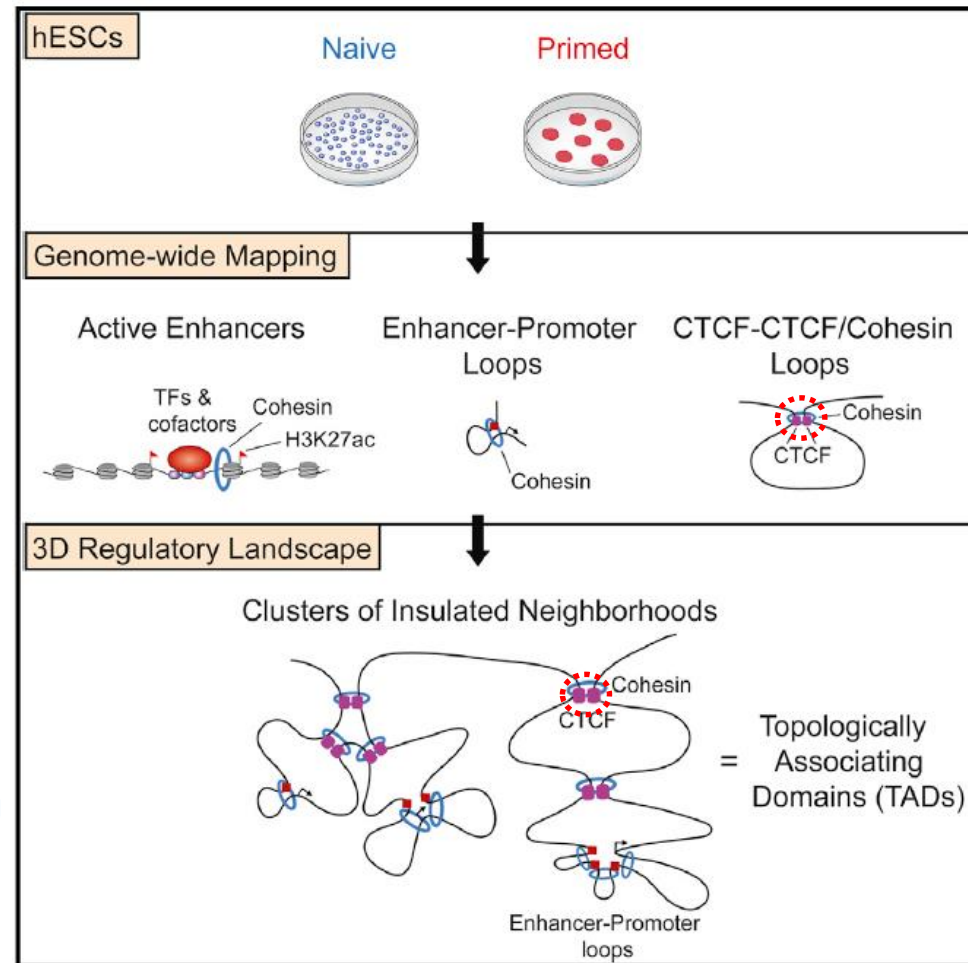

**Figure 1.** Models of chromatin organization. A diagram of different models of chromatin organization in the nuclear space. Interphase chromatin that interacts with the nuclear lamina (grey), nucleolus (green), nuclear pores (red), transcription factories (orange) and splicing speckles (black) are depicted here. Generally, lamin- and nucleolar-associated domains are transcriptionally repressed and have a more condensed chromatin, whereas chromatin that loops to the nuclear pore, transcription factories and splicing speckles are transcriptionally active and therefore have a more open chromatin structure (here, depicted as 10 nm chromatin fibre). Enhancers can activate gene expression over a distance and contain binding sites for TFs that recruit co-factors (activators or repressors). A promoter-enhancer looping mechanism mediated by cohesin (brown), CTCF (purple) and the mediator complex (red) that brings the enhancer into close proximity to its target promoter are presented in the enlarged box. The enhancer and promoter are marked with white boxes, and the transcription start site of the transcribed target gene is annotated with an arrow. TFs (green) and co-factors (yellow) bind the enhancer and are brought close to the basal transcription machinery at the promoter. RNAPolIII (orange) transcribes pre-mRNA from the target gene and eRNA from the enhancer. Some of these models may co-exist for different PEIs; however, there are also other models that we could not show. A colour version of this figure is available online at BIB online: <https://academic.oup.com/bib>.

# 3D Genome: Chromatin Interactions

Ji et al. map the chromosome organizational structures that underlie gene regulation in human naive and primed pluripotent cells. Their framework of cohesin-associated CTCF loops, and the cohesin-associated enhancer-promoter loops within them, provides a reference map for future interrogation of regulatory interactions.

- ChIA-PET analysis maps enhancers and insulators into looped domains
  - Cohesin-associated loops organize topologically associating domains (TADs)
  - Regulatory changes during cell state transitions take place within TADs
- The conserved anchors of CTCF-CTCF loops are frequently mutated in cancer

Young<sup>1,2,\*</sup>

# 3D Genome: Chromatin Interactions

**Figure 1. Schematic diagram of regulatory re-wiring following the deletion of a domain boundary.** (A) Interactions between enhancers and their target genes occur within chromatin domains. The deletion of a boundary region leads to novel gene-enhancer interactions between previously insulated elements; this process may lead to the spatial or temporal mis-expression of genes. (B) The same scenario as in (A) is drawn as represented by a high-throughput chromosome conformation capture (Hi-C) interaction map. Red triangles: topologically associating domains; yellow boxes: regulatory elements; blue boxes: target genes; green circles: insulator elements. Further examples of pathogenic genomic rearrangements, including insulator-spanning tandem duplications, are illustrated in 31.

# 3D Genome: Chromatin Interactions

## Disruption of Topologically Associating Domain (TAD) Structure Causes Congenital Disease

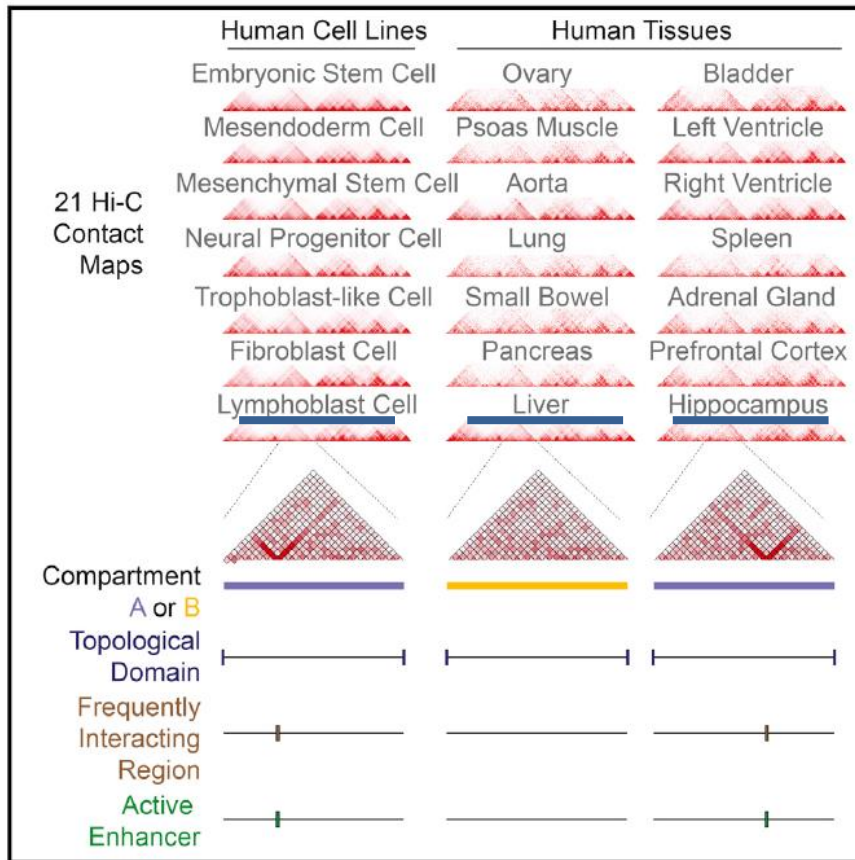

**Figure 3.** (A) F syndrome is a rare dominantly inherited skeletal disorder characterized by syndactyly of the first and second fingers. **An inversion leaves the TAD boundary intact but places a cluster of limb enhancers from a neighboring TAD in front of WNT6 causing misexpression in digit 1 and 2.** (B) Autosomal-dominant adult-onset demyelinating leukodystrophy (ADLD) is a rare neurological disorder characterized by progressive central nervous system demyelination due to overexpression of LMNB1. **A 600-kb deletion including a TAD boundary was shown to result in pathological interactions between three strong forebrain enhancer elements and the LMNB1 promoter resulting in cerebral lamin B1 overexpression and myelin degeneration.** (C) Structural variations can alter the TAD architecture of the genome by deleting, duplicating, or inverting TADs and their boundaries, thereby allowing enhancers from neighboring domains to ectopically activate genes causing misexpression and disease. **Deletions on chromosome 6p22.3 have been shown to cause mesomelic dysplasia featuring hypoplastic tibiae and fibulae. The deletions span three TADs and remove two TAD boundaries. This brings several potential limb enhancers into close proximity with ID4, presumably resulting in misexpression in the developing limb bud.**

## Tissue Specificity

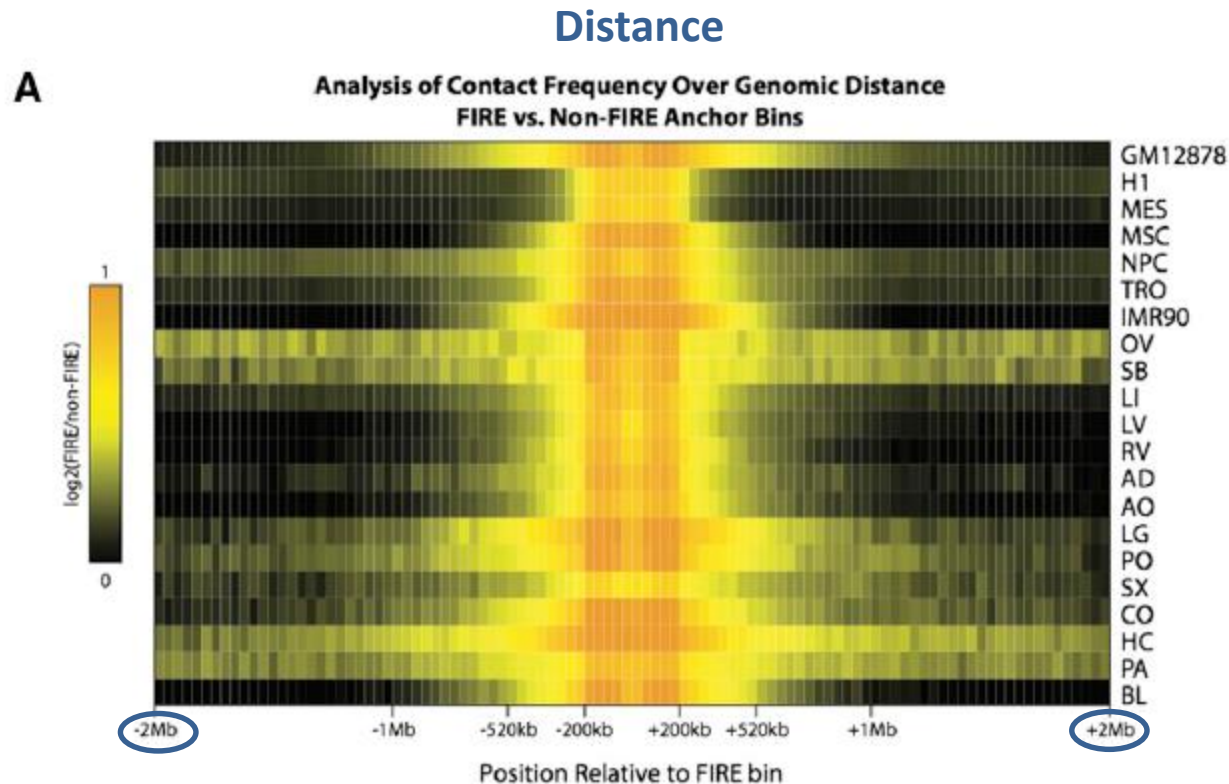

## In Brief

Schmitt et al. analyze Hi-C maps in 21 human cell lines and primary tissues and uncover a class of genome organizational features termed FIREs. FIREs are local interaction hotspots, highly tissue-specific, and correspond to active enhancers. We discuss the implications of our findings for the study of gene regulation and disease. Explore the Cell Press IHEC web portal at <http://www.cell.com/consortium/IHEC>.

## Highlights

- Integrative analysis of chromatin architecture in a broad set of human tissues
- FIREs are an architectural feature of chromatin organization
- FIREs are enriched for super-enhancers and show tissue-specific chromatin interactions
- FIRE formation is partially dependent on CTCF and the Cohesin complex

# 3D Genome: Chromatin Interactions

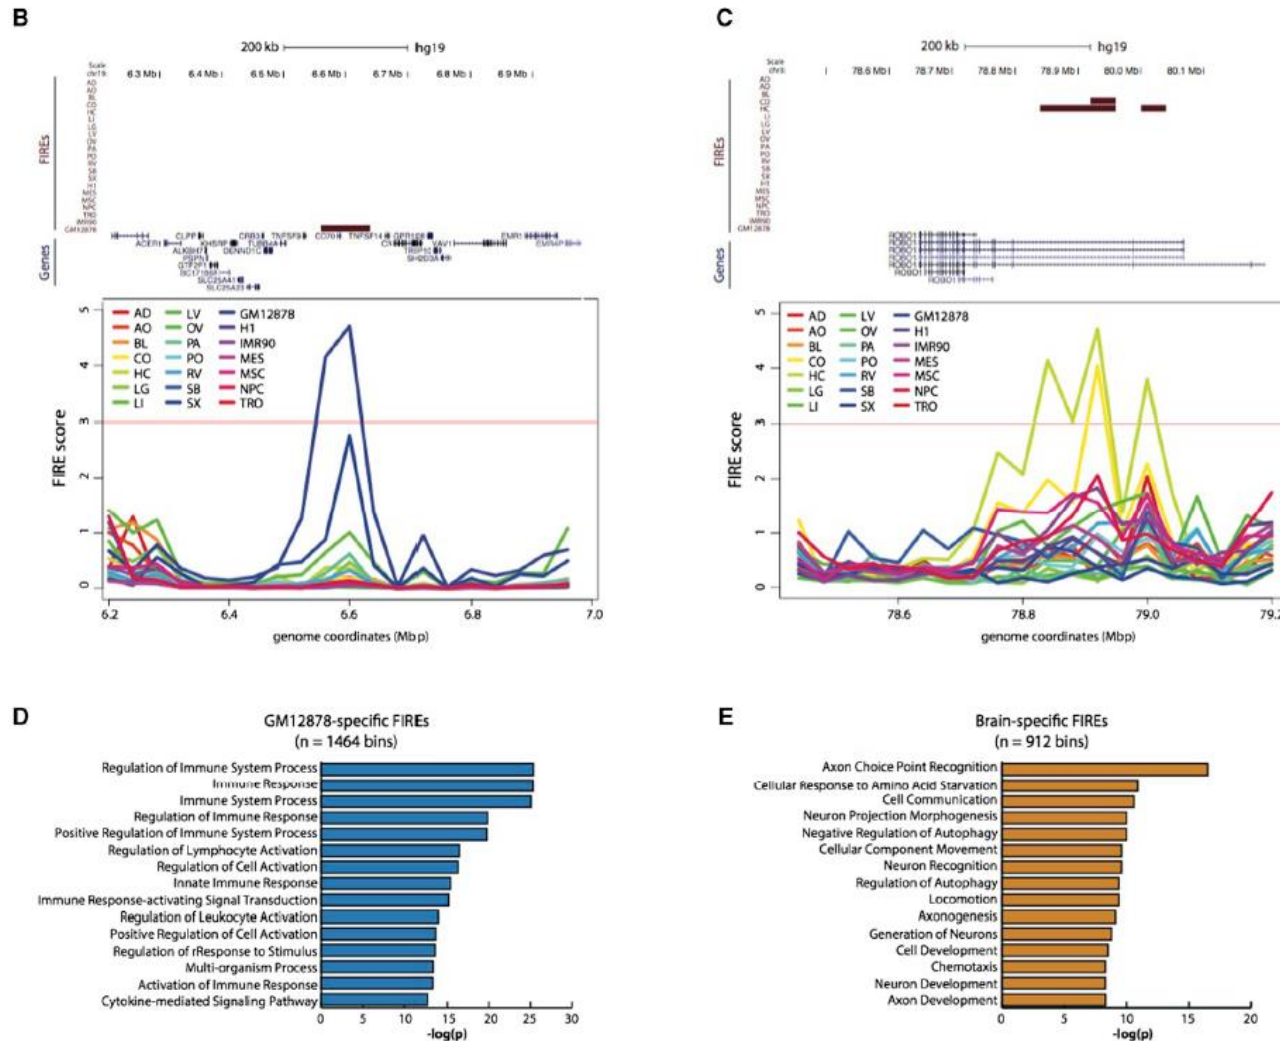

**Figure 7. FIREs Have Several Targets and Are Self-Interactive**

(A) Heat map showing the relationship between the mean observed contact frequencies at FIREs compared to the mean observed contact frequency at non-FIREs. Enrichment is shown as the ratio between the two contact observed mean contact frequencies (FIRE:non-FIRE) per unit genomic distance, from  $\pm 40$  kb to  $\pm 2$  Mb, centered on FIRE bins. Each row represents the analysis of a different sample, and the color intensity corresponds to the enrichment value.

# 3D Genome: Chromatin Interactions

## Tissue Specificity

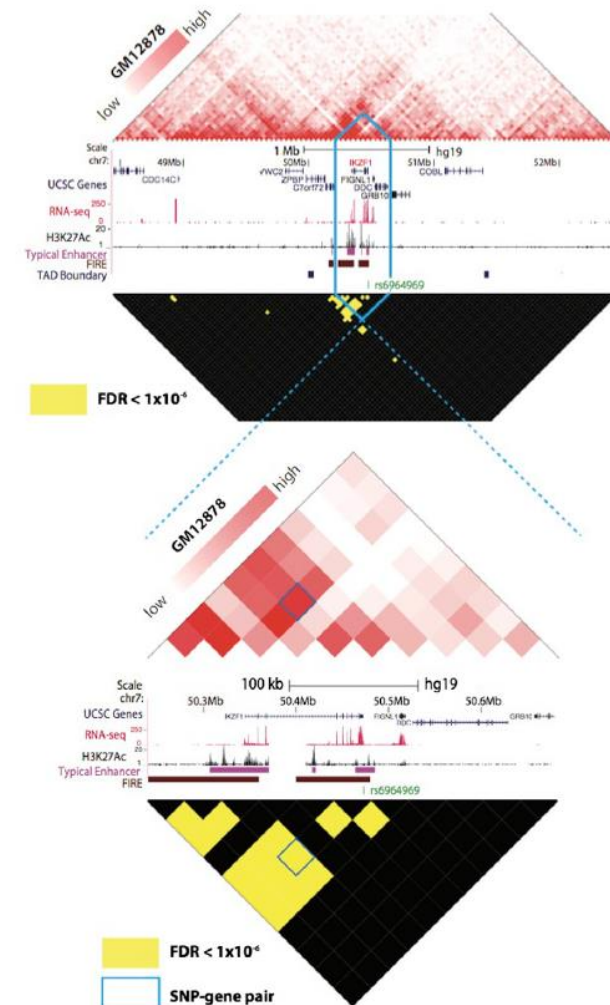

**Figure 3. FIREs are Tissue-type Specific and Enriched Near Genes Involved in Tissue Function**  
 (A) At the top is a dendrogram resulting from a hierarchical clustering analysis using genome-wide FIRE scores for each sample. The y axis is the Euclidean distance between FIRE scores from any two samples. The heat map below shows a subset of FIRE bins ( $n = 8,371$ ), corresponding to FIRE bins that are called as FIRE in only one or two samples. For ventricle tissues, brain tissues, IMR90/MS, and H1/MS, FIREs specific to two samples are allowed in the definition of sample specific.  
 (B) Genome browser snapshot showing a GM12878-specific FIRE region (chr19:6,560,000-6,640,000) (top, maroon) in an 800-kb region around *CD70* (chr19:6,583,193-6,604,114). Below is a line plot of FIRE scores for each sample, showing the GM12878-specific FIRE peak (blue).  
 (C) Genome browser snapshot showing a brain-specific FIRE region (chr3:78,920,000-79,960,000), shared by CO and HC, in a 760-kb region within *ROBO1* (chr3:78,646,338-79,068,609). Below is a line plot of FIRE scores for each tissue showing CO (yellow) and HC (pea green) FIRE peaks.  
 (D) GREAT biological process analysis of genes surrounding GM12878-specific FIRE bins ( $n = 1,464$  bins), showing biological processes highly related to immune functions. Plotted values are the  $-\log_{10}$  of the Bonferroni-corrected binomial  $p$  values.  
 (E) Same as (D), except using genes surrounding brain (CO and HC) specific FIRE bins ( $n = 912$  FIRE bins) showing several significant processes highly related to brain functionality. Plotted values are the  $-\log_{10}$  of the Bonferroni-corrected binomial  $p$  values.

# 3D Genome: Chromatin Interactions

## Disease Associations

### FIREs Are Enriched for Disease-Associated SNPs

Our analyses have indicated that FIREs are enriched for active enhancers and super-enhancers (Figures 4A–4D; Figures S3B, S3C, S3F, S3G, S3N, and S3O). Because typical and super-enhancers contain a significant proportion of disease-associated SNPs (Hnisz et al., 2013), we further investigated the overlap between FIREs and disease-associated SNPs. First, we mapped 4,327 previously annotated disease-associated non-coding SNPs to FIREs defined in each cell line and tissue (see Supplemental Experimental Procedures) (Hnisz et al., 2013). Consistent with previous results (Hnisz et al., 2013), we observed 7.06 and 3.76 SNPs per megabase, and among 354 GM12878 FIREs overlapped with super-enhancers and 2,800 GM12878 FIREs overlapped with typical enhancers, respectively (Figure S5A). Surprisingly, among 1,615 GM12878 FIREs that do *not* overlap an annotated enhancer, we also observed 3.33 SNPs per megabase, which is  $\sim 2.3$ -fold higher than the genome-wide SNP density (1.42 SNPs per megabase) (Figure S5A). Importantly, these SNPs would not be captured by directly overlapping super-enhancers or typical enhancers with disease-associated SNPs (Hnisz et al., 2013).

**Figure 6. FIREs Are Enriched with Disease-Associated GWAS SNPs**

(A) Heat map showing the enrichment of disease-associated GWAS SNPs (see [Supplemental Experimental Procedures](#)) in FIRE bins for each cell line or tissue (columns). Rows represent the enrichment of disease-associated SNPs for one disease, and all rows in the presented heat map are sorted from high to low based on enrichment score in GM12878 (lymphoblast cell line). Only diseases with >15 SNPs are shown. Noted to the right are the top 15 diseases for which disease-associated SNPs are most enriched in GM12878 FIREs, showing the high enrichment of several diseases (all except mean corpuscular volume) with previously noted immune-mediated pathology ([Jostins et al., 2012](#)).

(B) Normalized Hi-C contact matrix of a 2.16-Mb locus (chr1:65,120,000–67,280,000) in GM12878 cells. The tracks below depict the presence of two SNPs associated with acute lymphoblastic leukemia (rs546784 and rs6683977) located within a FIRE bin (brown, chr1:66,760,000–66,800,000), ~30 kb outside of a GM12878-specific super-enhancer (red) and also within the *PDE4B* gene sequence. To the right of the Hi-C contact matrix is the FIRE score.

(C) Bar plots showing the enrichment of Parkinson's disease-associated SNPs across 14 primary adult tissue FIRE annotations, also highlighting the highest enrichment in FIREs from both brain tissues (CO and HC).

(D) Bar plots showing the enrichment of SNPs associated with the quantitative triglycerides trait across 14 primary adult tissue FIRE annotations, also highlighting the highest enrichment in liver FIREs.

(E) Normalized Hi-C contact matrix (top) in GM12878 for a 4.04-Mb locus (chr7:48,440,000–52,480,000) centered on *IKZF1* (red text). The Hi-C color scale ranges from the 15<sup>th</sup> to 99<sup>th</sup> percentile normalized contact frequencies within this locus. The reflected matrix shows the statistically significant (FDR < 1e–6) bin-pairs within 2-Mb genomic distance across the locus. Only bin pairs with FDR < 1e–6 are yellow; the rest are black. Between the matrices are a UCSC gene annotations (blue, top), RNA-seq data (red), H3K27Ac data (black), typical enhancer annotations ([Hnisz et al., 2013](#)) (purple), FIRE annotations (brown), TAD boundary calls (blue), and an SNP that is statistically linked to the *IKZF1* TSS (green). The blue lines outline the 440-kb locus (chr7:50,240,000–50,680,000) that is shown in (F).

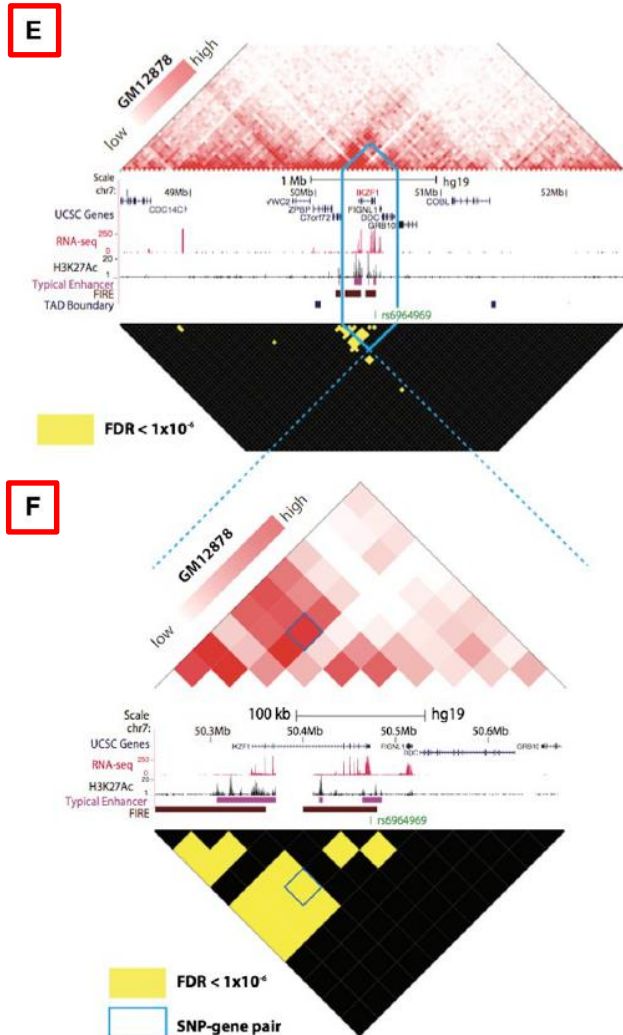

(F) Same as (E), except a zoomed-in snapshot of a 440-kb locus (chr7:50,240,000–50,680,000) centered on a SNP-bearing FIRE bin (chr7:50,440,000–50,480,000) containing the 3' UTR of *IKZF1* and the SNP rs6964969. The blue box outlines the bin pair that is the significant interaction between previously known SNP-gene pairs.

(G) Bar plots showing the enrichment of liver GTEx eQTLs in FIRE peak bin pairs as a function of the subset of top liver FIRE peaks (based on the lowest false discovery rate) determined by Fit-Hi-C.

(H) Same as (G), except using aorta GTEx eQTLs, FIREs, and FIRE peaks.

(I) Same as (G), except using left ventricle GTEx eQTLs, FIREs, and FIRE peaks.

(J) Same as (G), except using cortex GTEx eQTLs, FIREs, and FIRE peaks.

## *FTO* rs1421085

**Chr16:53703963..54114467**

Claussnitzer and colleagues recently showed that the *FTO* allele, which shows the strongest genome wide association signal for obesity, acts a gain of function. Using CRISPR/Cas9 genome editing, they showed that the disease-associated single-nucleotide variant rs1421085 T to C disrupts a conserved motif for the *ARID5B* repressor, which unleashes a pre-adipocyte enhancer, leading to a doubling of *IRX3* and *IRX5* expression during early adipocyte differentiation.

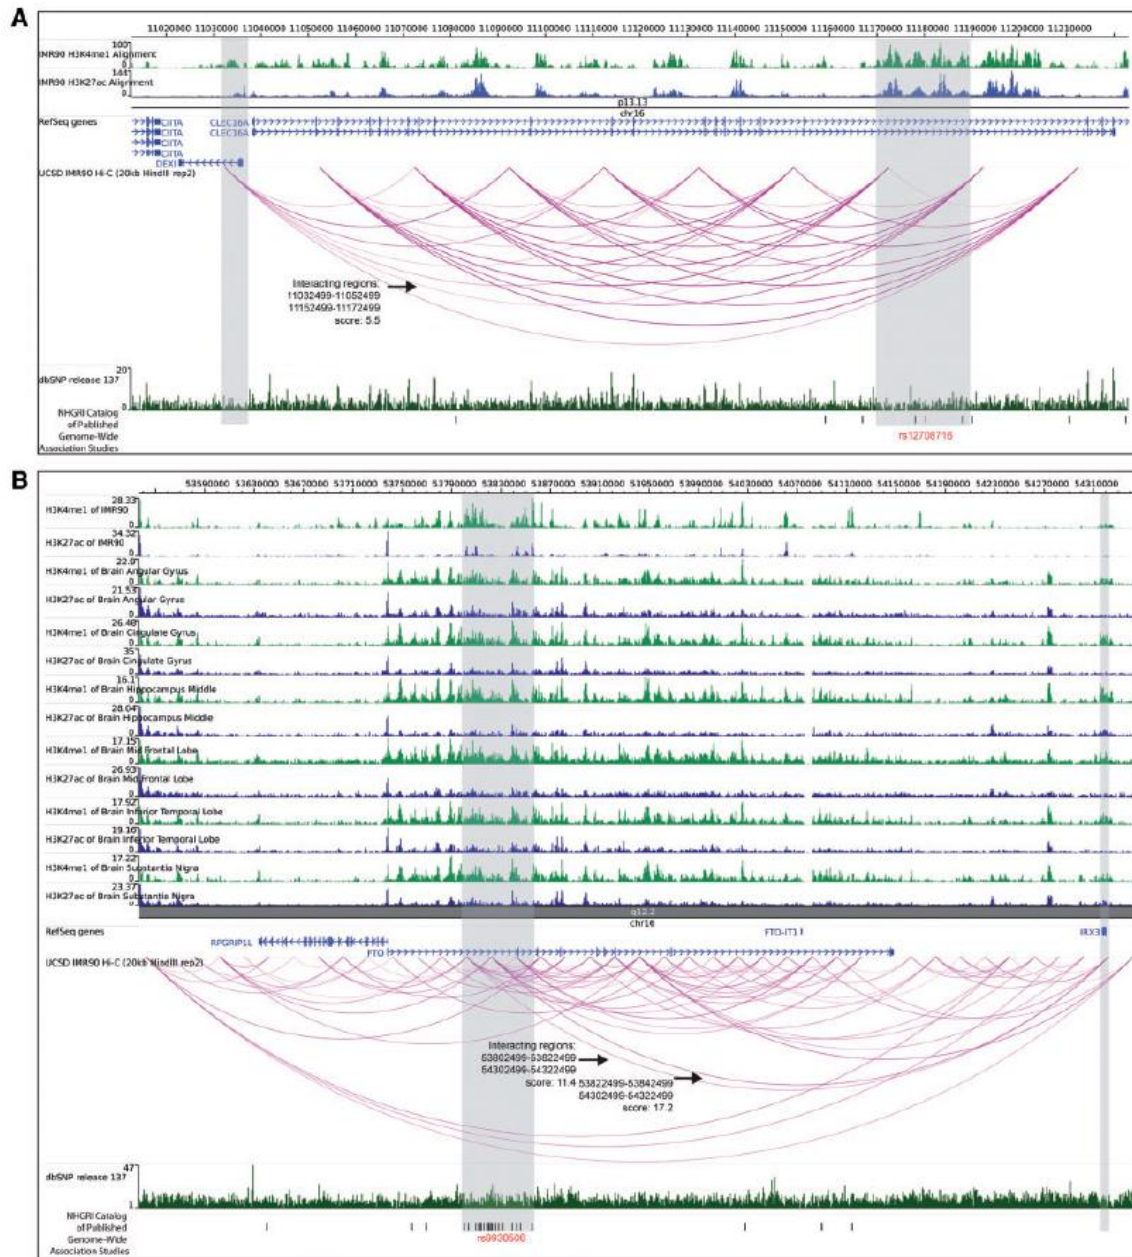

# 3D Genome: Chromatin Interactions

**Figure 2. Activation of *IRX3* and *IRX5* Expression in Human Adipocyte Progenitors by the *FTO* Obesity Risk Genotype.** **Panel A** shows gene annotations and LD with array tag variant rs9930506 in a 2.5-Mb window; LD is expressed as  $r^2$  values in the CEU population. Arrows indicate the direction of transcription of annotated genes in the locus. **Panel B** shows chromosome conformation capture (Hi-C) interactions contact probabilities in human IMR90 myofibroblasts, revealing a 2-Mb topologically associating domain, and LD mean  $r^2$  statistics for all SNV pairs at 40-kb resolution. **Panel C** shows box plots for expression levels, after 2 days of differentiation, in human adipose progenitors isolated from 20 risk-allele carriers and 18 non-risk-allele carriers, evaluated by means of a quantitative PCR analysis for all genes in the 2.5-Mb locus. The horizontal line within each box represents the median, the top and bottom of each box indicate the 75th and 25th percentile, and I bars indicate the range.

# 3D Genome: Chromatin Interactions

**Figure 1:** Long-range interactions functionally connect disease-associated SNPs with disease candidate genes. (A) Physical proximity between DEX1 gene locus and autoimmune disease-associated SNPs in the intron of DEX1 (from the Ren lab, [85]) show interactions between CLEC16A intron 19 and the DEX1 locus. The enhancer marks in IMR-90 cells for H3K4me1 and H3K27ac are shown in green and blue, respectively, and the filter threshold for the Hi-C data was set to 5. SNPs in the region are in black, and the eQTL SNP rs12708716 is marked in red. The arc (pink) for interacting regions (grey) is highlighted with an arrow. (B) Long-range interactions links obesity-associated variants in FTO with the IRX3 locus. Hi-C data in human foetal lung (IMR-90) cells show interactions between the first intron of FTO with IRX3. The tracks for H3K4me1 and H3K27ac are shown in green and blue from IMR-90 cells and different human brain tissues from the NIH Roadmap Epigenomics Mapping Consortium. The filter threshold for the Hi-C data was set to 10. SNPs in the region are in black, and the BMI-associated SNP rs9920500 is marked in red. Arcs (pink) for interacting regions (grey) are highlighted with arrows. These public data sets are available and visualized with the WashU EpiGenome Browser (<http://epigenomegateway.wustl.edu/browser/>), dbSNP release 137 is shown in dark green, and the The National Human Genome Research Institute (NHGRI) Catalogues of GWAS are visualized in UCSC browser (<http://genome-euro.ucsc.edu>) [166]. A colour version of this figure is available online at <https://academic.oup.com/bib>.

## SNCA rs356168

Parkinson's disease protective allele:

Efficient TF binding  
Decreased SNCA expression  
Decreased Parkinson's disease risk

Parkinson's disease risk allele:

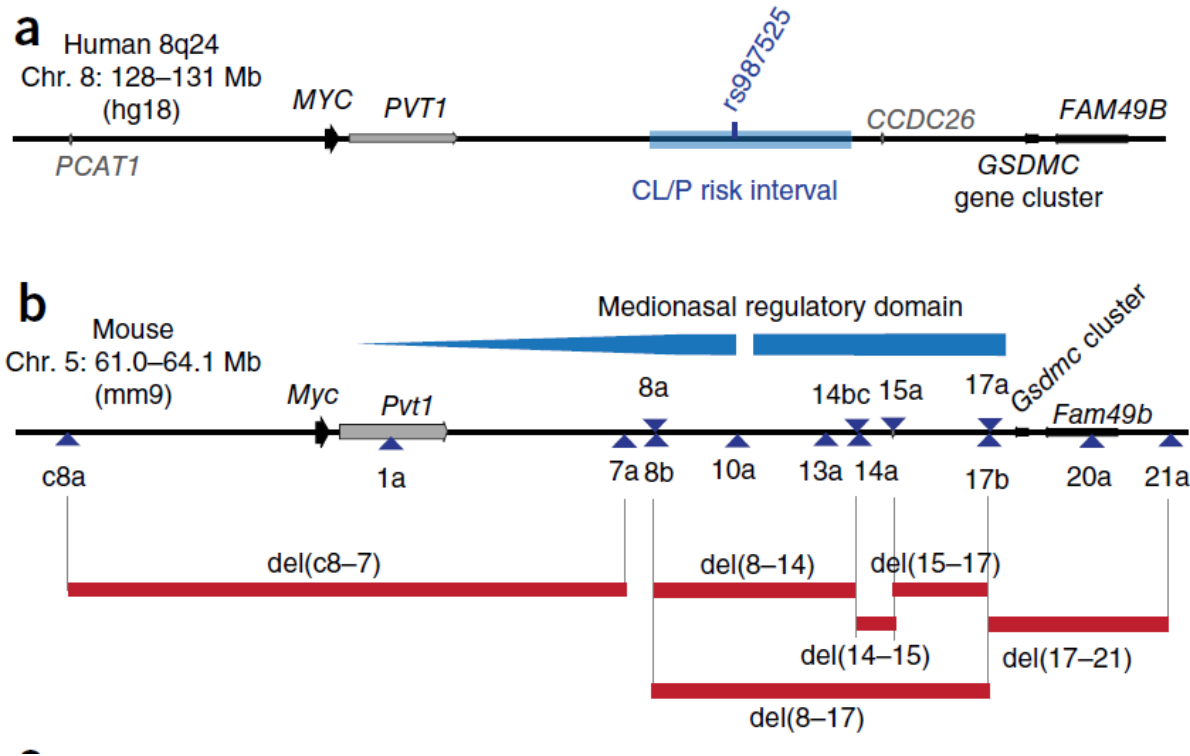

Reduced TF binding  
Increased SNCA expression  
Increased Parkinson's disease risk

**Figure 4 | Proposed model describing the correlation between SNP-dependent TF binding, SNCA expression and Parkinson's disease risk.** Carriers of the A allele at rs356168 (Parkinson's disease protective allele) show efficient binding of the brain-specific TFs EMX2 and NKX6-1 at the distal intron-4 enhancer, which results in a suppressed distal enhancer and consequently lower expression of SNCA associated with a reduced risk to develop Parkinson's disease. In contrast, carriers of the G allele at rs356168 (Parkinson's disease risk allele) show reduced TF binding, which results in an active distal enhancer leading to increased expression of SNCA and increased risk of developing Parkinson's disease.

# 3D Genome: Chromatin Interactions

## In Brief

Tan et al. identify and characterize 69 human complex trait/disease-associated lincRNAs in LCLs. They show that these loci are often associated with *cis*-regulation of gene expression and tend to be localized at TAD boundaries, suggesting that these lincRNAs may influence chromosomal architecture.

- We identify 69 lincRNAs associated with human complex traits (TR-lincRNAs)
- TR-lincRNAs are conserved in humans and interact with other disease-relevant loci
- TR-lincRNAs often associate with *cis*-regulation of proximal protein-coding gene expression
- TR-lincRNAs are enriched at TAD boundaries and may modulate chromatin architecture

## *cis*-Acting Complex-Trait-Associated lincRNA Expression Correlates with Modulation of Chromosomal Architecture

## Spotlight

Enhancer-Derived lncRNAs Regulate Genome Architecture: Fact or Fiction?

Stephanie Fanucchi<sup>1,2,\*</sup> and Musa M. Mhlanga<sup>1,2,\*</sup>

How does the non-coding portion of the genome contribute to the regulation of genome architecture? A recent paper by Tan *et al.* focuses on the relationship between *cis*-acting complex-trait-associated lincRNAs and the formation of chromosomal contacts in topologically associating domains (TADs).

**Figure 1. *Cis*-Acting TR-lincRNAs May Influence Target Gene Expression by Altering Intra-TAD Chromosomal Looping.** (A) By using GWAS *cis*-eQTL analysis, Tan *et al.* [8] identified regulatory interactions between *cis*-acting TR-lincRNAs and target genes. TADs containing TR-lincRNAs display a higher density of chromosomal contacts. TR-lincRNAs are often located near the boundaries of TADs and arise from enhancer regions. (B) TR-lincRNAs were shown to be occupied by cohesin, but not by CTCF. (C) Possible TR-lincRNA mode(s) of action. TR-lincRNAs may (i) regulate chromosomal looping directly; (ii) use chromosomal looping to bring protein binding partners, such as transcriptional regulators or chromatin remodelers, in close proximity to target genes; or (iii) act as miRNA decoys. Abbreviations: ChIP-seq; chromatin immunoprecipitation with deep sequencing; CTCF, CCCTC-binding factor; eQTL, expression quantitative trait locus; GWAS, genome-wide association study; HSK4me1/3, histone H2 lysine 4 mono/trimethylation; lincRNA, long intergenic non-coding RNA

An intronic polymorphism of IRF4 gene influences gene transcription *in vitro* and shows a risk association with childhood acute lymphoblastic leukemia in males

Thuy N. Do, Esma Ucisik-Akkaya, Charronne F. Davis, Brittany A. Morrison, M. Tevfik Dorak \*

Genomic Immunoepidemiology Laboratory, HUMIGEN LLC, The Institute for Genetic Immunology, 2439 Kuser Road, Hamilton, NJ 08690-3303, USA

**Fig. 1.** IRF4 intron 4 with wild type allele C at SNP rs12203592 represses IRF4 promoter activity while IRF4 intron 4 with variant allele T significantly alleviates this repressive effect. Both work in an orientation- and position-independent manner. The full 1.2-kb fragment of intron 4 of the human IRF4 gene (contains either a wild type C or variant allele T at SNP rs12203592) was subcloned into the luciferase-reporter plasmid driven by a 2.4-kb IRF4 promoter (the big black arrow right before luciferase gene (LUC)). In all of the constructs, the LUC is used as a reporter gene whose mRNA is stabilized by a polyadenylation/splice signal from the simian virus 40 (Poly A). Raji cells were co-nucleofected with these constructs and with the internal control plasmid pGL4.13[hRenilla/SV40] and then assayed for both firefly and *Renilla* luciferases after 24 h. To adjust for differences in transfection efficiencies, firefly luciferase values were standardized to *Renilla* luciferase values. The results are from three independent experiments. The error bars represent standard errors. \*Comparison between intron 4 with the variant allele T and intron 4 with the wild type allele C; #comparison between CD(+)/CtoT with TD(+).

## Allele-specific transcriptional regulation of *IRF4* in melanocytes is mediated by chromatin looping of the intronic rs12203592 enhancer to the *IRF4* promoter

Mijke Visser, Robert-Jan Palstra<sup>†</sup> and Manfred Kayser<sup>\*</sup>

Department of Forensic Molecular Biology, Erasmus MC University Medical Centre Rotterdam, Wytemaweg 80, 3015 CN Rotterdam, The Netherlands

The rs12203592 enhancer physically interacts with the *IRF4* promoter through an allele-dependent chromatin loop.

# 3D Genome: Chromatin Interactions

The rs12203592 enhancer physically interacts with the *IRF4* promoter through an allele-dependent chromatin loop.

Figure 7. Proposed model for the chromatin conformation of the *IRF4* locus and subsequent transcriptional regulation of *IRF4*, depending on the allelic status of rs12203592 in melanocytes and melanoma cells. The pigmentation-associated SNP rs12203592 is located in intron 4 of *IRF4* and the region around this SNP functions as an enhancer element. The transcription factor TFAP2 $\alpha$  acting as sequence specific DNA binding factor recognizes the rs12203592 enhancer in an allele-dependent manner, which then allows for the recruitment of the transcription factors MITF, YY1 and potential additional transcription factors like LEF1. Chromatin loops are formed between the rs12203592 enhancer and the *IRF4* promoter as well as the intron-7 YY1-element, both interactions depend on the allelic status of rs12203592. With the C-allele present, TFAP2 $\alpha$  binds the rs12203592 enhancer, followed by recruitment of additional factors like MITF, YY1 and potentially LEF1, loop formation and proper transcriptional activation of the *IRF4* gene. The T-allele is unable to bind TFAP2 $\alpha$ , which leads to reduced recruitment of additional factors, reduced loop formation and diminished *IRF4* expression in skin melanocytes. The different interactions between the rs12203592 enhancer and the *IRF4* promoter (as well as the intron-7 YY1-element) could be the result of a shift in equilibrium between the unfolded and interacting state that depends on the rs12203592 alleles, which is indicated by the double, opposite-directed arrows. In the G361 melanoma cell line, the TFAP2 $\alpha$  factor presumably still binds the rs12203592 enhancer and loop formation toward the *IRF4* promoter is established; however, the loop toward the intron-7 YY1 element is disrupted, resulting in a less stable chromatin structure and consequently, diminished expression of *IRF4*. In the BLM melanoma cell line, MITF is absent and no chromatin loops are formed, resulting into a linear chromatin conformation and silenced *IRF4* expression.

Allele-specific transcriptional regulation of *IRF4* in melanocytes is mediated by chromatin looping of the intronic rs12203592 enhancer to the *IRF4* promoter

**GWAS3D**

Detecting Human Regulatory Variants by Combining Genome Wide Association Study and Chromosome Conformation

Introduction

GWAS3D

Help

About

Update!!

► GWAS3D

**news:** 06/10/2013 Improve HiC resolution to 10Kb for GM12878, K562, H1-hESC and RWPE1 cell types.

**news:** 30/05/2013 External browser now can be connected to HaploReg v2, Regulomedb, SNVrap and UCSC ENCODE Browser for candidate regulatory variants.

**news:** 09/04/2013 Feature enhancement: 1) Support adjusting the P-value for scanning putative TF binding sites; 2) Support the analysis without cell-type restriction.

► My Jobs

Welcome to the gateway of GWAS3D. Interpreting noncoding phenotypically associated variants is an indispensable step to understand molecular mechanism of complex traits, GWAS3D systematically compute the probability of genetics variants affecting regulatory pathways and underlying disease/trait associations by integrating chromatin state, functional genomics, sequence motif, and conservation information when given GWAS data or variant list. GWAS3D also provided comprehensive annotations and visualizations to help users interpreting the results. Please check detailed information on online help.

## Main Functions

- Identify the most probable functional variants which affect transcriptional regulation;
- Prioritize the leading variants when given a full list of GWAS result;
- Evaluate the deleteriousness of genetic variants affecting the gene regulation when given a list of variants;
- Annotate genetic variant from regulatory perspective.

## Chromatin Chromatin Space Interaction

[Home](#)[Method](#)[Search](#)[Download](#)[Help](#)[Update](#)

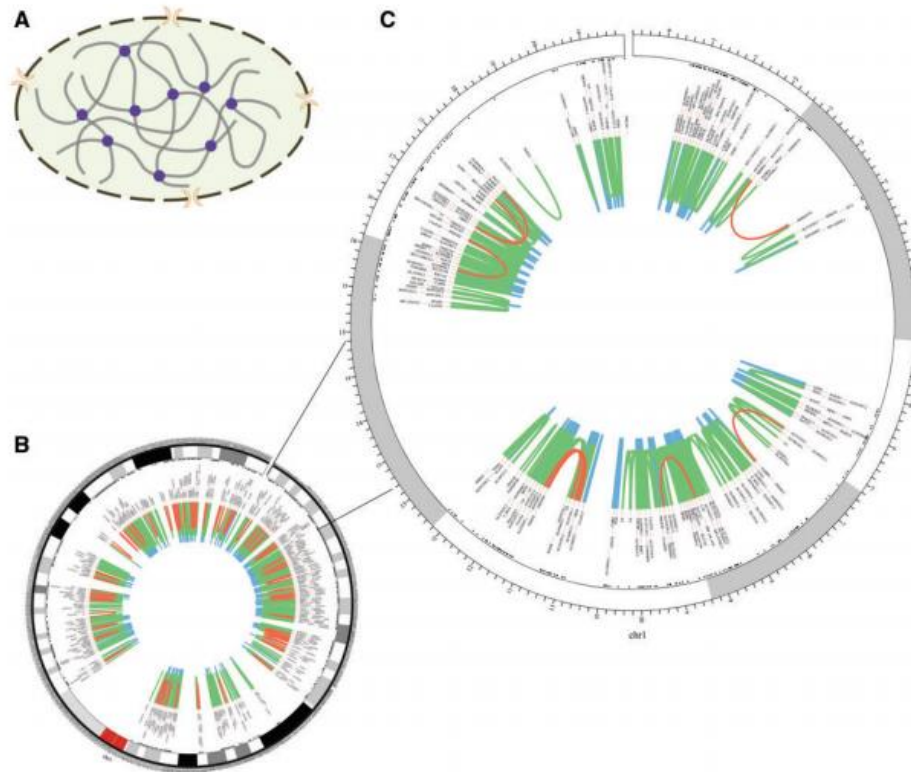

### Welcome to CCSI database

Here, **CCSI (Chromatin Chromatin Space Interaction)** database presents 3,017,962 chromatin interaction pairs with annotation of genes, enhancers and SNPs in many cell lines of human, mouse and yeast. These data were obtained by means of **3C, 4C, 5C, ChIA-PET and Hi-C** technology in a cell's natural state, nearly all of which detected the three-dimensional architecture of chromosome by coupling ligation in close spatial proximity followed by high-throughput sequencing. So transcriptional regulatory mechanism in disease pathogenesis associated with spatial interactions among genes, enhancers and SNPs could be explored on the base of it.

# Bioinformatics Tools

**Figure 2.** Chromosomal 3D structure and promoter–promoter interactions of Chr1 in IMR90 cell line based on a set of Hi-C data. **(A)** Chromosomal 3D structure. The dashed circle with two orange crescents that stand for nuclear pore complex is the nucleus membrane. The thick grey lines are chromatin and the purple circles stand for proteins that link chromatin together. **(B)** Promoter–promoter interactions of Chr1:1-200000000, zooming into the interactions. The red lines stand for long-range interactions (distance between interaction pair > 500 kb), while the blue lines for short-range (distance < 50 kb) and the green lines for middle-range (distance spanning 50–500 kb). The black texts are the gene names of corresponding loci.

ChIP-seq of GM12878

*Homo sapiens* GM12878

Target: IKZF2

Lab: Michael Snyder, Stanford

Project: ENCODE

Experiment  
ENCSR680UQE  
released  

2

ChIP-seq of GM12878

*Homo sapiens* GM12878

Target: POLR2A

Lab: Richard Myers, HAIB

Project: ENCODE

Experiment  
ENCSR000BGD  
released  

5

ChIP-seq of GM12878

*Homo sapiens* GM12878

Target: IKZF1

Lab: Michael Snyder, Stanford

Project: ENCODE

Experiment  
ENCSR874AFU  
released  

1

ChIP-seq of GM12878

*Homo sapiens* GM12878

Target: EED

Lab: Richard Myers, HAIB

Project: ENCODE

Experiment  
ENCSR100WKF  
released  

2

ChIP-seq of HL-60

*Homo sapiens* HL-60

Target: POLR2AphosphoS5

Lab: Richard Myers, HAIB

Project: ENCODE

Experiment  
ENCSR000BTL  
released

# Bioinformatics Tools

## HaploReg v4

HaploReg is a tool for exploring annotations of the noncoding genome at variants on haplotype blocks, such as candidate regulatory SNPs at disease-associated loci. Using LD information from the 1000 Genomes Project, linked SNPs and small indels can be visualized along with chromatin state and protein binding annotation from the Roadmap Epigenomics and ENCODE projects, sequence conservation across mammals, the effect of SNPs on regulatory motifs, and the effect of SNPs on expression from eQTL studies. HaploReg is designed for researchers developing mechanistic hypotheses of the impact of non-coding variants on clinical phenotypes and normal variation.

**Update 2015.09.15: Version 4** now includes many recent eQTL results including the GTEx pilot, four different options for defining enhancers using Roadmap Epigenomics data, and a complete set of source files for download and local analysis. Older versions available: [v3](#), [v2](#), [v1](#).

[Build Query](#) [Set Options](#) [Documentation](#)

Use one of the three methods below to enter a set of variants. If an  $r^2$  threshold is specified (see the Set Options tab), results for each variant will be shown in a separate table along with other variants in LD. If  $r^2$  is set to NA, only queried variants will be shown, together in one table.

Query (comma-delimited list of rsIDs OR a single region as chrN:start-end):

or, upload a text file (one refSNP ID per line):

[Browse...](#)

or, select a GWAS:

[Submit Query](#)

Query SNP: **rs6964969** and variants with  $r^2 \geq 0.8$

# Conclusions

**GWAS has fulfilled the aim of unraveling disease biology more than providing markers for disease prediction**

**Unexpected results in gene deserts and other intergenic regions shed light on the function of these non-coding regions**

**What used to be called “junk DNA” codes for non-coding RNA and involved in chromatin interactions**

**Non-coding genetic variants modify the function of regulatory elements as crucially as coding variants alter protein structure**

**Projects like ENCODE, NIH Epigenomics Road Map and BluePrint provide sufficient data to examine effects of genetic variation**

# Conclusions

**The data indicate that the target gene of a genetic variation may be far away from it (even on a different chromosome); the nearest gene is unlikely to be the target gene**

**The target genes are usually tissue-specific**

**The candidate genes involved in a disease process may not have a variation of itself implicated in the disease development**
